# Motivation : The Modelling Domain

Modelling Domain

Inputs  
are Models

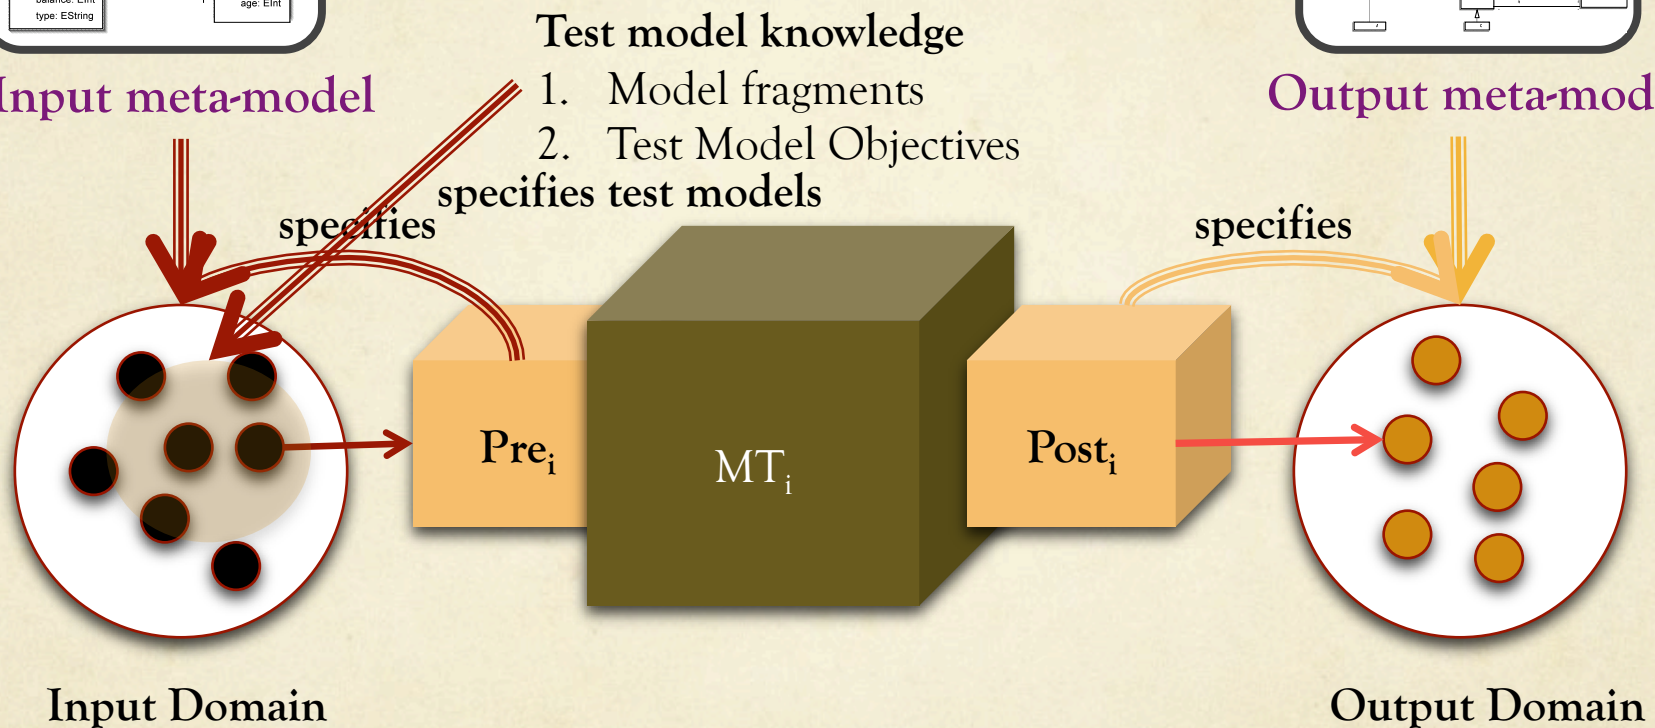

# Motivation : Transformations

Input meta-model

Output meta-model

**Question:** How to select test models using knowledge from *Input meta-model* +  $Pre_i$  + *Test Model Knowledge*?

# Motivation : Applications

1. *Model transformation pipelines such as XML to XML Pipelines (Eg: Xproc)*
2. *Code Generators (Eg: Simulink Model to Code)*
3. *Object Persistence (Eg: Hibernate 3.0)*
4. *Simulation Traces (Eg: Simulink, Modelica)*
5. *UML Model Design Re-factoring (Eg: Rhapsody)*
6. *Code migration (Cobol to Java/C#, VPLUS UI to XML/J2EE )*
7. *Game development pipelines (Eg: XNA Studio)*
8. *Business Process Models (Eg: Websphere business process model)*
9. *Code reverse engineering*
10. *Graphical Editors ...*

# Challenge: Effective Domains

To select a model (a complex graph) from a *constrained infinite* domain

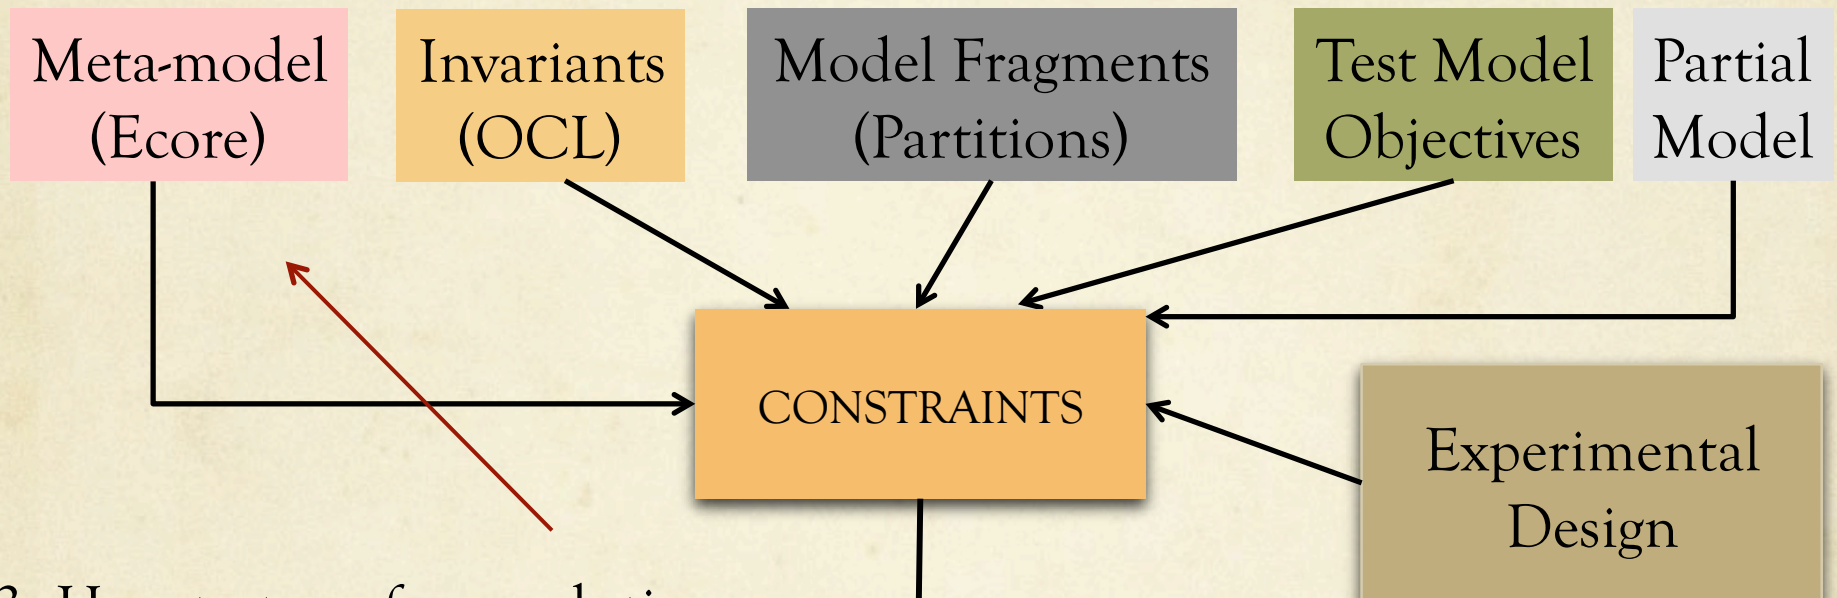

Unbounded number of Transitions

# Challenge: Building Effective Modelling Domains for Testing

1. How to transform sources of knowledge for testing?

3. How to transform solutions to modelling domain instance?

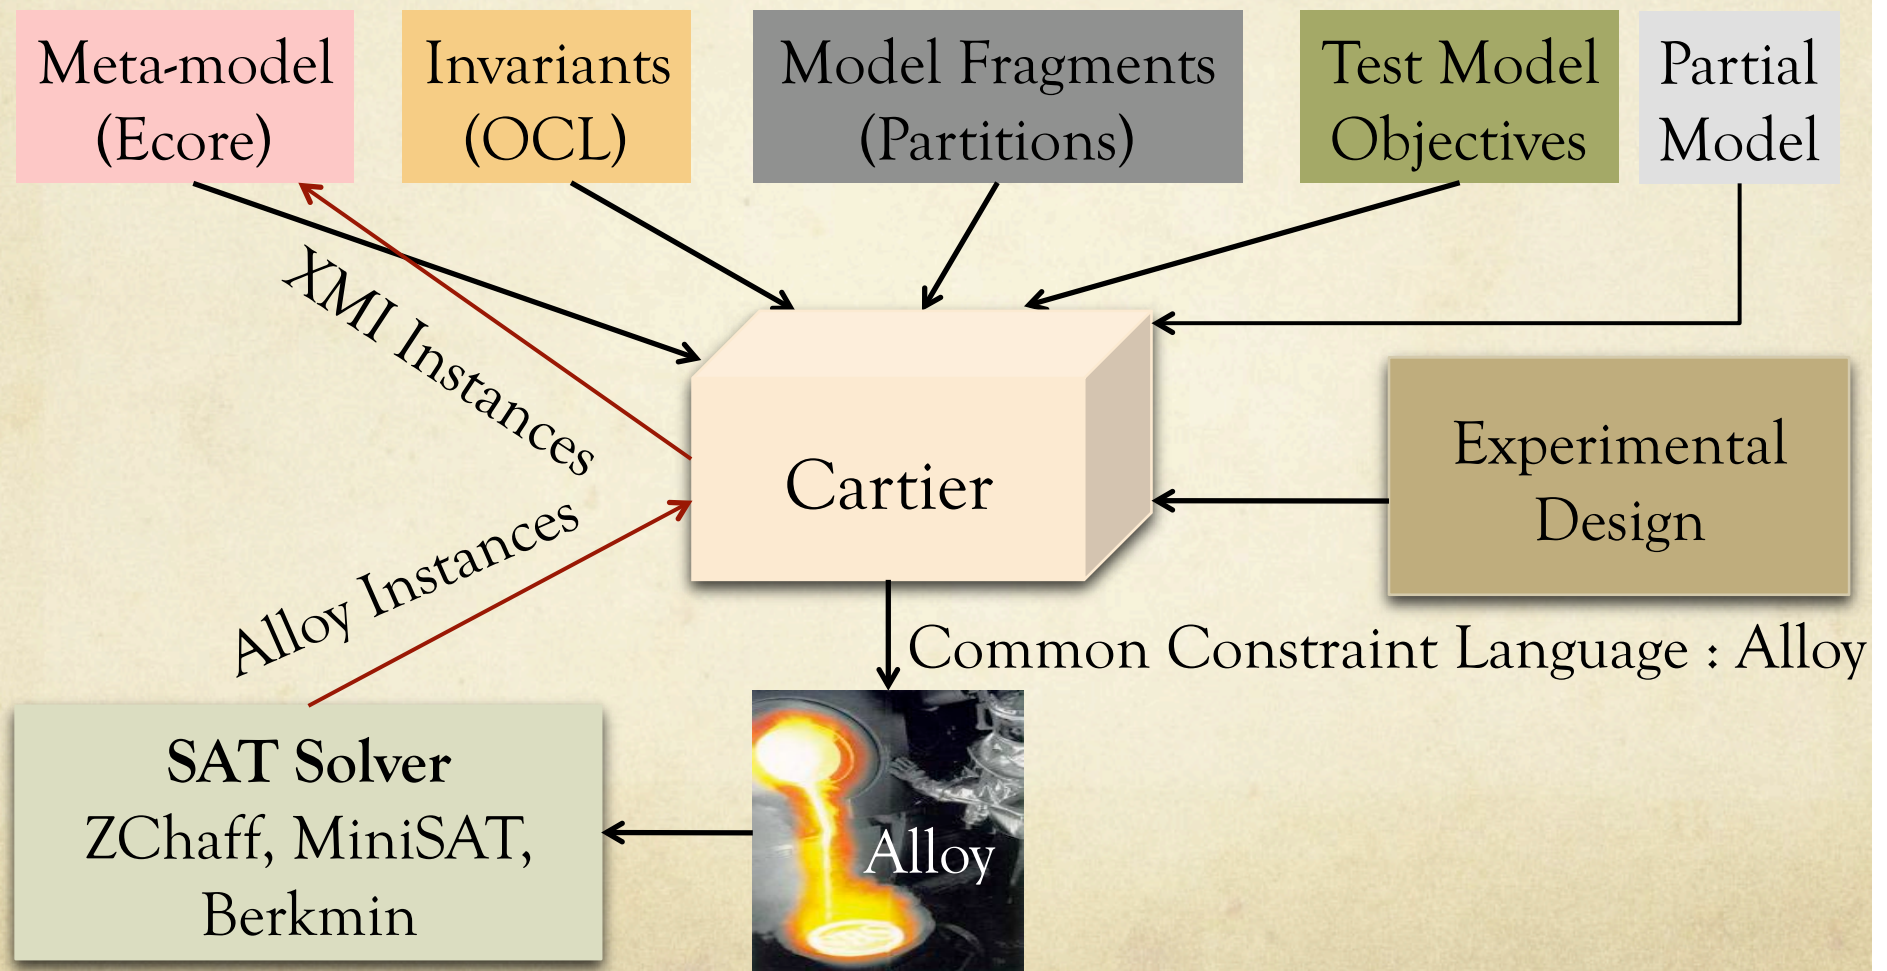

2. How to solve and which solver?

# Solution Overview: Cartier

## 1. Transformation from Knowledge Sources to Alloy

# Cartier : A Guided Tour

Cartier is implemented using Kermeta  
(<http://www.kermeta.org>)

- ❑ Kermeta (Meta-modelling Kernel) is a language to represent meta-models and models of the different sources of knowledge.
- ❑ Cartier uses “aspect-oriented modelling” to transform *aspects* in source language to target language Alloy.
- ❑ So, what are the essential aspects in Kermeta that are transformed to Alloy ? ....

# Cartier : A Guided Tour

1. Kermeta Meta-model to  
Alloy Base Model

2. Test Model Knowledge  
to  
Alloy Predicates

3. Experimental Design  
to  
Alloy Run Commands

# Cartier: A Guided Tour (Object Persistence Case Study)

Transformed to an Alloy  
Signature

```

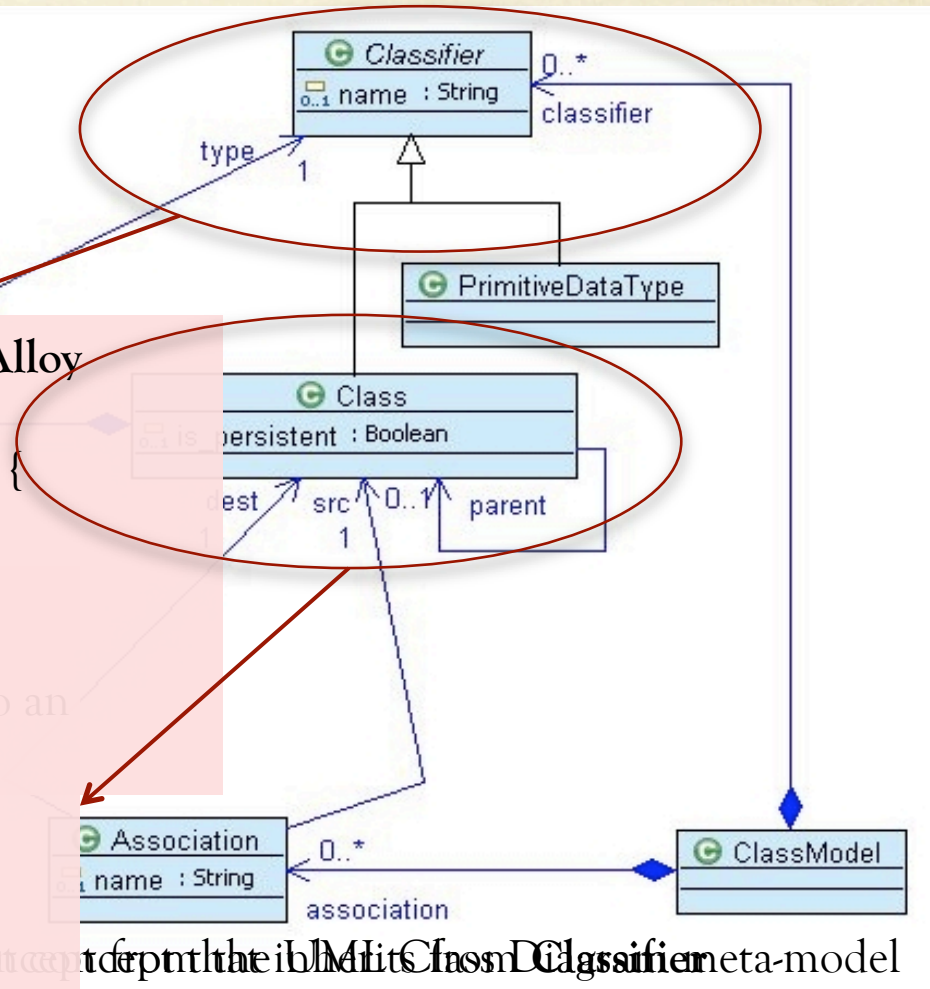

abstract sig Classifier {
  name : Int
  }
  
```

Transformed to an Alloy  
Signature

String is abstracted to an  
integer for simplicity

```

sig Class extends Classifier {
  is_persistent: one Bool,
  parent : lone Class,
  attrs : some Attribute
}
  
```

to capture the IBM UML Class Classifier meta-model

# Cartier: A Guided Tour

## Transforming Invariants

No Cyclic Inheritance

OCL Version:

context Class:

inv :

not self.allParents()->includes(self)

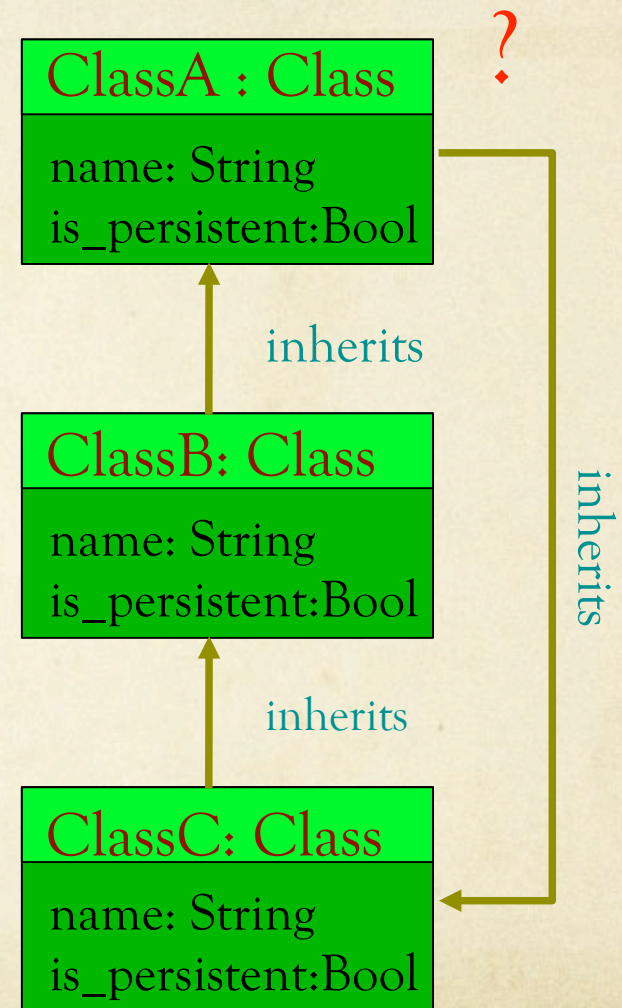

↓ to an Alloy fact (specified for a subset)

Alloy Version:

```
fact noCyclicInheritance {
```

```
    no c: Class | c in c.^parent
```

```
}
```

# Cartier : A Guided Tour

1. Kermeta Meta-model to  
Alloy Base Model

2. Test Model Knowledge  
to  
Alloy Predicates

3. Experimental Design  
to  
Alloy Run Commands

# Cartier : A Guided Tour

## Transforming Model Fragments

Consider the model fragment (partition of the modelling domain)  
obtained using MMCC (Frank Fleurey et al. 2007) on the UML  
Class Diagram meta-model

Association(source=0) and Association(source =1)

*At least one Association object with no source and one Association object  
with one source*

transformed to  
an Alloy predicate

```
pred modelFragment1
{
  some a1:Association,a2:Association | #a1.src=0 and #a2.src=1
}
```

# Cartier : A Guided Tour

1. Kermeta Meta-model to  
Alloy Base Model

2. Test Model Knowledge  
to  
Alloy Predicates

3. Experimental Design  
to  
Alloy Run Commands

# Cartier : A Guided Tour

## Transforming Experimental Design

**A experimental design specifies:**

- 1) A factorial combination of number of objects of each type and different predicates.
- 2) Scope of Integer, String
- 3) Maximum size of a sequence

to Alloy Run Commands

run testModel1 for exactly 10 Class, exactly 5 Attribute, exactly 10 Association,  
5 Int

run testModel1 for exactly 10 Class, exactly 10 Attribute, exactly 10 Association,  
5 Int

.

run testModel2 for exactly 5 Class, exactly 5 Attribute, exactly 10 Association, 5  
Int

# Cartier : A Guided Tour

## Instance Generation and Output Processing

### Alloy API Calls

1. Load output Alloy model

2. Parse Alloy model

3. Generate Boolean CNF

4. Select Boolean SAT Solver

5. Solve CNF and Dump XML

6. Transform XML to XMI

# Instance Generation using Alloy

## *Why Alloy?*

- ❑ Combines the power of first-order predicate logic with quantifiers and operators in relational logic.
- ❑ A restricted but theoretically sound meta-level declarative language.
- ❑ Operators such as transitive closure improve the expressive power of Alloy over for example Prolog

*Eg: A constraint can be expressed on:*

$c.^{\wedge}parent = \{c.parent, c.parent.parent, c.parent.parent.parent, \dots\}$

- ❑ Operators such as the relational join (box/dot) allow you to specify powerful navigation expressions on sets and relations.

*Eg:*

$all\ c: State \mid c.label \neq 5$

- ❑ Automatic transformation to Boolean CNF for instance and counterexample generation for a finite scope.

# Instance Generation using Alloy

## *Some limitations*

- ❑ No support for higher-order relations.
- ❑ That means no constraint on relations of relations
- ❑ Constraints can be expressed on binary relations and their transitive closure.
- ❑ No fundamental support for String type from the MDE world. We developed one.
- ❑ No extensive support for functions on relations. Functions in Alloy are named expressions.

# Instance Generation using Alloy

- For a given scope or exact number of objects Alloy creates relations which are tuples of atoms.

*Example:*

```
sig Association {  
  name: Int,  
  dest: one Class,  
  src: one Class  
}
```

```
Association = {  
  (14, Class8, Class4),  
  (11, Class8, Class9),  
  (8, Class8, Class3),  
  (1, Class7, Class5),  
  (-10, Class6, Class9),  
  (-14, Class5, Class3),  
  (-16, Class5, Class6),  
  (-16, Class5, Class2),  
  (-1, Class4, Class1)  
}
```

run mfAllRanges6a for 1 ClassModel, 5 int, exactly 10 Class,  
exactly 20 Attribute, exactly 4 PrimitiveDataType, exactly 10 Association

# Instance Generation using Alloy

```
Association = {  
  (14, Class8, Class4),  
  (11, Class8, Class9),  
  (8, Class8, Class3),  
  (1, Class7, Class5),  
  (-10, Class6, Class9),  
  (-14, Class5, Class3),  
  (-16, Class5, Class6),  
  (-16, Class5, Class2),  
  (-1, Class4, Class1)  
}
```

Where do these values come from?

That satisfies facts such as...

```
/* An associations have the same name either  
they  
are the same association or they have  
different sources*/  
fact uniqueNameAssocSrc {  
  all a1:Association, a2:Association |  
  a1.name == a2.name => (a1 = a2 or a1.src !=  
  a2.src)  
}
```

# Instance Generation using Alloy

```

a[1..10] = {
  (v1,v2,v3),
  (v4,v5,v6),
  (v7,v8,v9),
  (v10,v11,v12),
  (v13,v14,v15),
  (v16,v17,v18),
  (v19,v20,v21),
  (v22,v23,v24),
  (v25,v26,v27),
  }

```

# Validation : Mutation Analysis

Question: Are the generated test models able to detect bugs?

(Mottu, J.; Baudry, B. & Traon, Y. L.

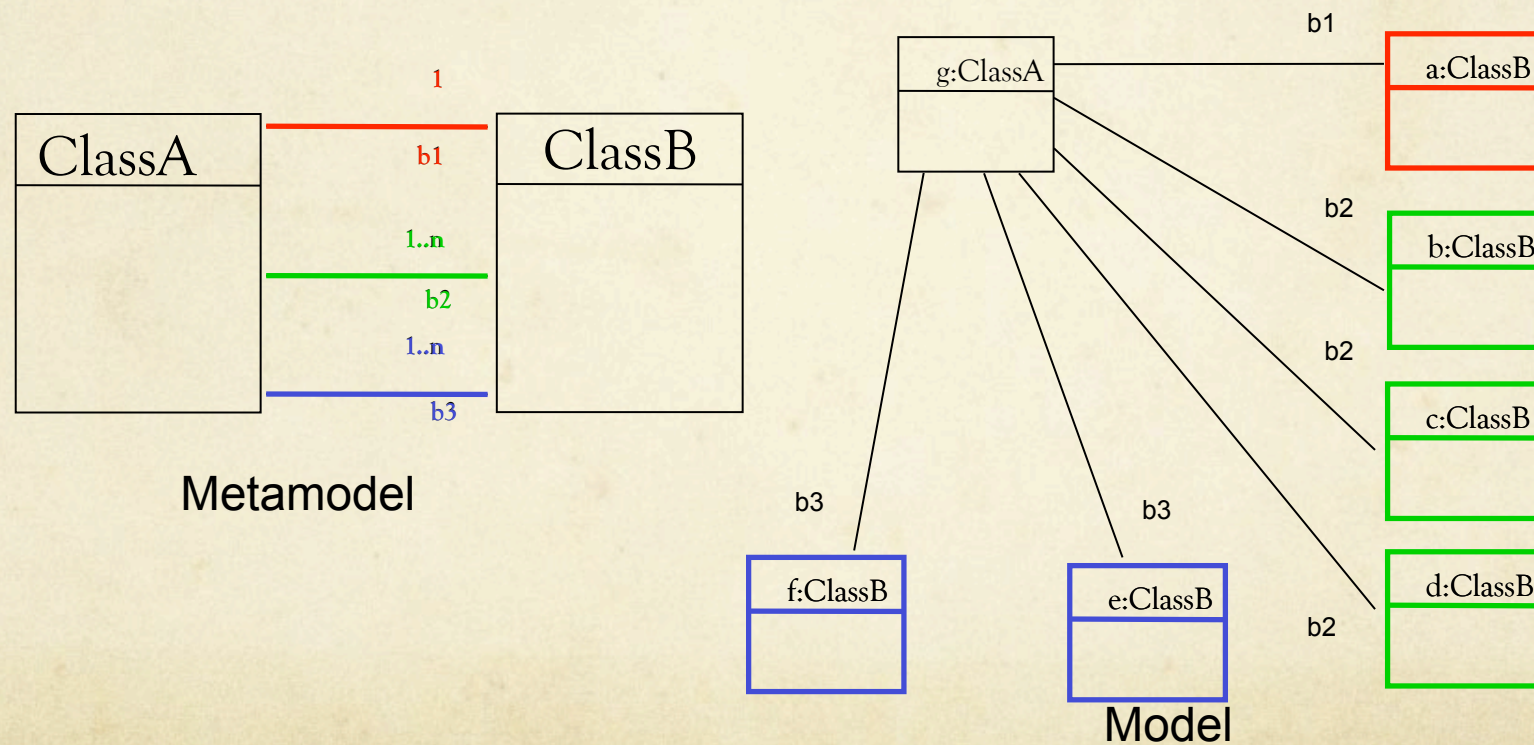

Mutation Analysis Testing for Model Transformations

*Proceedings of ECMDA'06 (European Conference on Model Driven Architecture), 2006)*

# Validation : Mutation Analysis

## A Navigation Mutation Operator Example

- Relation to the Same Class Change - RSCC

# Experiments and Results

## Experimental Design

**Objective:** To compare test generation strategies using mutation scores of sets of test models:

- a) Using model fragments and conforming to modelling domain
- b) Randomly selected in a pool of models of various sizes conforming to modelling domain.

We compare four strategies for model selection : AllRanges, Random(15 models/set), AllPartitions, Random(5 models/set)

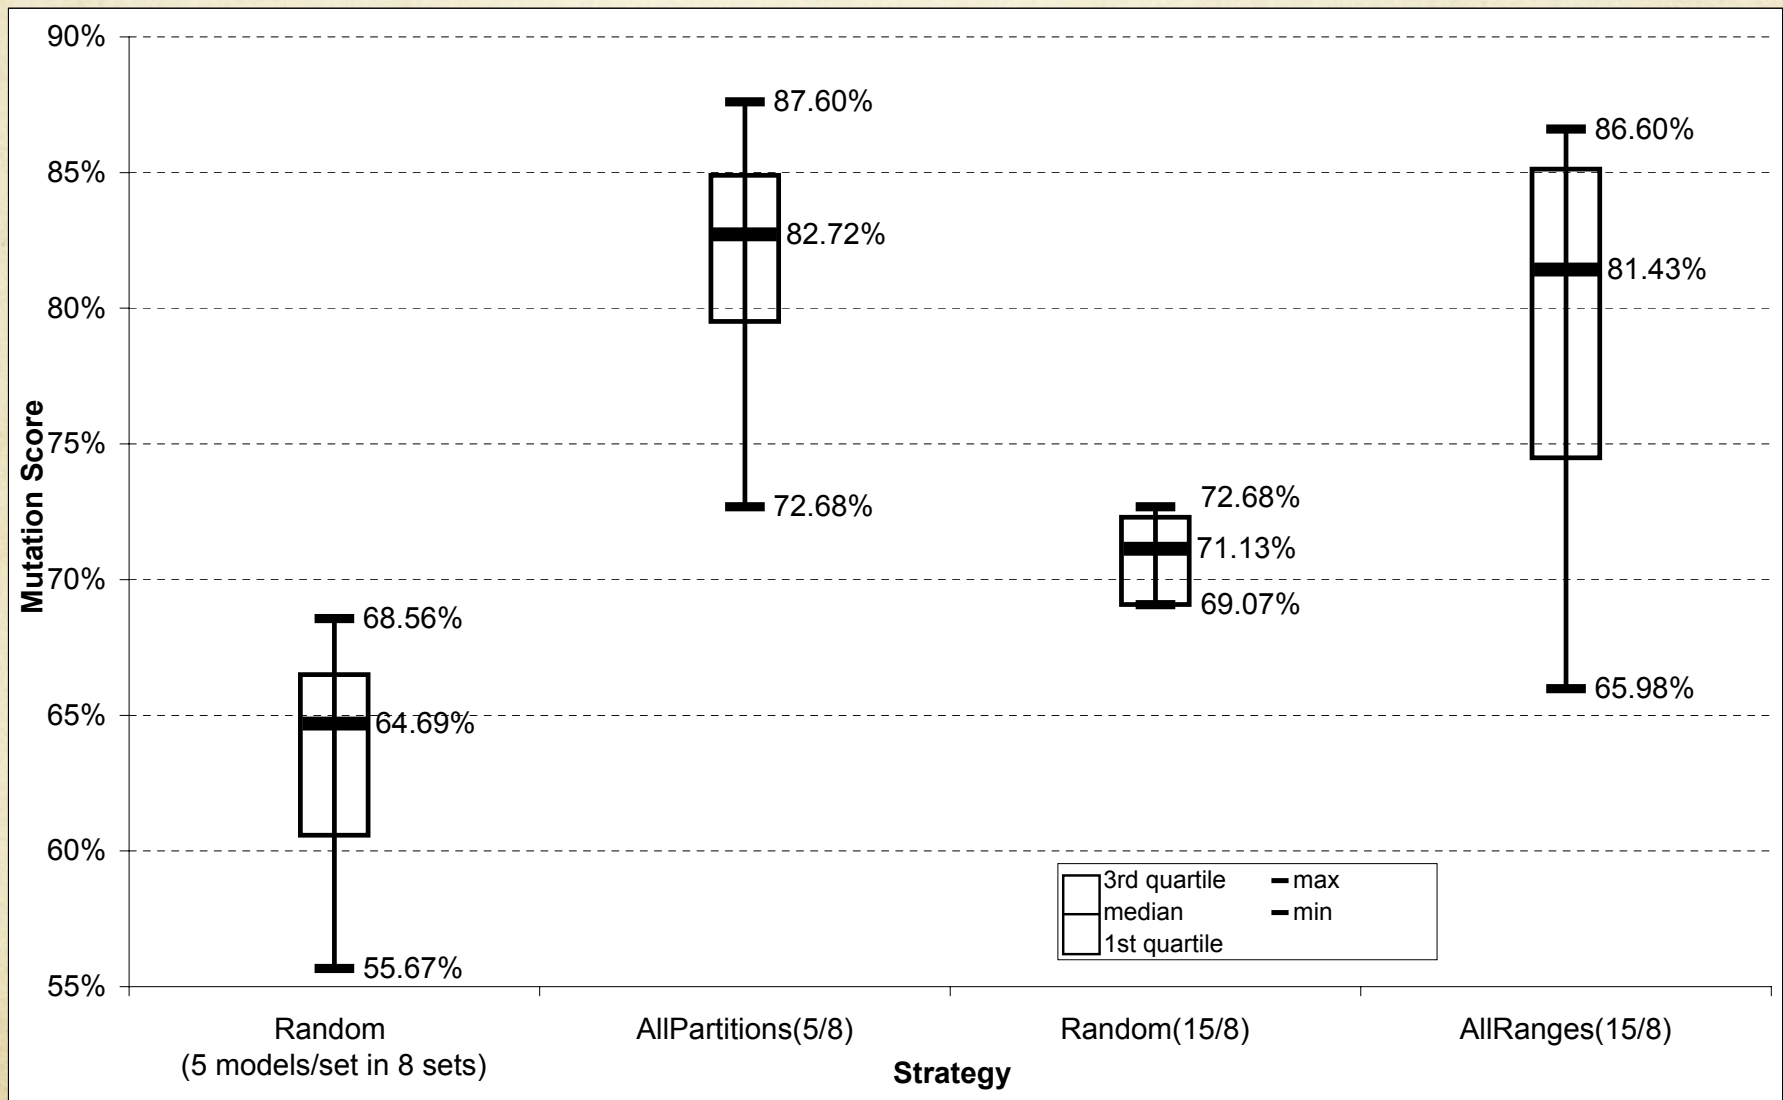

Models Generated for AllRanges =  $8 \times 15 = 120$

Models Generated for AllPartitions =  $8 \times 5 = 40$

Models Generated for Random = 200

Total = 360 models

# Experiments and Results

# Conclusion

- We present a tool Cartier to transform a modelling domain to Alloy
- We show how we invoke the Alloy API to generate instances or models.
- We show how the effectiveness of these generated instances can be improved for testing using test model knowledge such as model fragments.
- We want to apply Cartier and Alloy for several applications in MDE such as test generation, partial model completion, and improving modelling domain specifications.
